$$p_t(\mathbf{x}|\mathbf{x}_1) = q_{1-t}(\mathbf{x}|\mathbf{x}_0 = \mathbf{x}_1)$$

Variance Exploding SDE
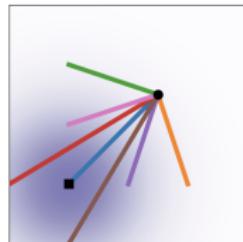

$$p_t(\mathbf{x}|\mathbf{x}_1) = \mathcal{N}\left(\mathbf{x}_1, \sigma_{1-t}^2\mathbf{I}\right) \quad \Rightarrow \quad \mathbf{f}(\mathbf{x}, \mathbf{x}_1, t) = -\frac{\sigma'_{1-t}}{\sigma_{1-t}}(\mathbf{x}_t - \mathbf{x}_1)$$

- ▶ **Discrete time** $t \in \{0, 1, \ldots, T\}$.
- ▶ **Continuous time** $t \in [0, 1]$.

Key advantages of discrete diffusion

- ▶ Parallel generation
- ▶ Flexible infilling

- ▶ Unified framework

Recap of Previous Lecture

Discrete Diffusion Markov Chain

$$q(\mathbf{x}_t|\mathbf{x}_{t-1}) = \mathrm{Cat}(\mathbf{Q}_t\mathbf{x}_{t-1}),$$

Each $\mathbf{x}_t \in \{0,1\}^K$ is a **one-hot vector** encoding the categorical state (it is just one token).

Transition Matrix

$$[\mathbf{Q}_t]_{ij} = q(x_t = i|x_{t-1} = j), \qquad \sum_{i=1}^{K}[\mathbf{Q}_t]_{ij} = 1.$$

$$q(\mathbf{x}_t|\mathbf{x}_0) = \mathrm{Cat}(\mathbf{Q}_{1:t}\mathbf{x}_0), \qquad \mathbf{Q}_{1:t} = \mathbf{Q}_t\mathbf{Q}_{t-1}\cdots\mathbf{Q}_1.$$

▶ The choice of $\mathbf{Q}_t$ determines how information is erased and what the stationary distribution becomes.

▶ $\mathbf{Q}_t$ and $\mathbf{Q}_{1:t}$ should be easy to compute for each t.

Recap of Previous Lecture

Uniform vs. Absorbing Transition Matrix

Aspect	Uniform Diffusion	Absorbing Diffusion
$\mathbf{Q}_t$	$(1-\beta_t)\mathbf{I} + \beta_t\mathbf{U}$	$(1-\beta_t)\mathbf{I} + \beta_t\mathbf{e}_m\mathbf{1}^\top$
$\mathbf{Q}_{1:t}$	$\bar{\alpha}_t\mathbf{I} + (1-\bar{\alpha}_t)\mathbf{U}$	$\bar{\alpha}_t\mathbf{I} + (1-\bar{\alpha}_t)\mathbf{e}_m\mathbf{1}^\top$
$\mathbf{Q}_{1:\infty}$	$\mathbf{U}$	$\mathrm{Cat}(\mathbf{e}_m)$
Interpretation	Random replacement	Gradual masking of tokens
Application	Image diffusion	Text diffusion $\approx$ Masked LM

Observation

Both schemes gradually destroy information, but differ in their stationary limit. Absorbing diffusion bridges diffusion and masked-language-model objectives.

ELBO

$$\mathcal{L}_{\phi,\theta}(\mathbf{x}) = \mathbb{E}_{q(\mathbf{x}_1|\mathbf{x}_0)} \log p_\theta(\mathbf{x}_0|\mathbf{x}_1) - \mathrm{KL}\big(q(\mathbf{x}_T|\mathbf{x}_0)\|p(\mathbf{x}_T)\big) -$$

$$- \sum_{t=2}^{\top} \underbrace{\mathbb{E}_{q(\mathbf{x}_t|\mathbf{x}_0)} \mathrm{KL}\big(q(\mathbf{x}_{t-1}|\mathbf{x}_t,\mathbf{x}_0)\|p_\theta(\mathbf{x}_{t-1}|\mathbf{x}_t)\big)}_{\mathcal{L}_t}$$

Discrete conditioned reverse distribution

$$q(\mathbf{x}_{t-1}|\mathbf{x}_t,\mathbf{x}_0) = \mathrm{Cat}\left(\frac{\mathbf{Q}_t\mathbf{x}_t \odot \mathbf{Q}_{1:t-1}\mathbf{x}_0}{\mathbf{x}_t^\top \mathbf{Q}_{1:t}\mathbf{x}_0}\right).$$

▶ Both $q(\mathbf{x}_{t-1}|\mathbf{x}_t,\mathbf{x}_0)$ and $q(\mathbf{x}_t|\mathbf{x}_0)$ are known analytically from the forward process.

▶ The reverse process $p_\theta(\mathbf{x}_{t-1}|\mathbf{x}_t)$ is a learned categorical distribution:

$$p_\theta(\mathbf{x}_{t-1}|\mathbf{x}_t) = \mathrm{Cat}\big(\boldsymbol{\pi}_\theta(\mathbf{x}_t, t)\big).$$

Austin J. et al., Structured denoising diffusion models in discrete state-spaces, 2021.

Recap of Previous Lecture

ELBO term
$$\mathcal{L}_t = \mathbb{E}_{q(\mathbf{x}_t|\mathbf{x}_0)}\mathrm{KL}\big(q(\mathbf{x}_{t-1}|\mathbf{x}_t,\mathbf{x}_0)\,\|\,p_{\boldsymbol{\theta}}(\mathbf{x}_{t-1}|\mathbf{x}_t)\big).$$

Categorical KL
$$\mathrm{KL}\big(\mathrm{Cat}(\mathbf{q})\,\|\,\mathrm{Cat}(\mathbf{p})\big) = \sum_{k=1}^{K} q_k \log \frac{q_k}{p_k} = \mathrm{H}(\mathbf{q},\mathbf{p}) - \mathrm{H}(\mathbf{q}),$$

▶ $\mathrm{H}\big(q(\mathbf{x}_{t-1}|\mathbf{x}_t,\mathbf{x}_0)\big)$ is a constant w.r.t. $\boldsymbol{\theta}$.
▶ $\mathrm{H}(\mathbf{q},\mathbf{p}) = -\sum_k q_k \log p_k$ is a **cross-entropy loss**.

Therefore, minimizing $\mathcal{L}_t$ w.r.t. $\boldsymbol{\theta}$ is equivalent to minimizing

$$\mathbb{E}_{q(\mathbf{x}_t|\mathbf{x}_0)}\mathrm{H}\Big(q(\mathbf{x}_{t-1}|\mathbf{x}_t,\mathbf{x}_0),\,p_{\boldsymbol{\theta}}(\mathbf{x}_{t-1}|\mathbf{x}_t)\Big).$$

Absorbing Diffusion

Conditioned reverse distribution

$$q(\mathbf{x}_{t-1}|\mathbf{x}_t, \mathbf{x}_0) = \begin{cases} [\mathbf{x}_{t-1} = \mathbf{x}_t], & \text{if } \mathbf{x}_t \neq \mathbf{e}_m, \\ \rho_t[\mathbf{x}_{t-1} = \mathbf{x}_0] + (1-\rho_t)[\mathbf{x}_{t-1} = \mathbf{e}_m], & \text{if } \mathbf{x}_t = \mathbf{e}_m, \end{cases}$$

where

$$\rho_t = \frac{\beta_t \, \bar{\alpha}_{t-1}}{1 - \bar{\alpha}_t}.$$

▶ If $\mathbf{x}_t \neq \mathbf{e}_m$, then the token must be unchanged: $\mathbf{x}_{t-1} = \mathbf{x}_t$.

- Observing an unmasked token at time t fixes the entire history: $\mathbf{x}_{t-1} = \mathbf{x}_t = \cdots = \mathbf{x}_0$.
- If $\mathbf{x}_t = \mathbf{e}_m$, the previous token may be either clean or masked.
- With probability ρ_t, masking occurred exactly at step t (so $\mathbf{x}_{t-1} = \mathbf{x}_0$).
- With probability $(1 - \rho_t)$, the token was already masked earlier (so $\mathbf{x}_{t-1} = \mathbf{e}_m$).

Absorbing Diffusion

Sequence Distribution

Each position i has two possible cases:

$$\mathbf{x}_t^i \neq \mathbf{e}_m \ \Rightarrow \ \mathbf{x}_{t-1}^i = \mathbf{x}_t^i, \qquad \mathbf{x}_t^i = \mathbf{e}_m \ \Rightarrow \ \mathbf{x}_{t-1}^i \in \{\mathbf{x}_0^i, \mathbf{e}_m\}.$$

Absorbing Diffusion

Sequence Distribution

$$q(\mathbf{X}_{t-1}|\mathbf{X}_t, \mathbf{X}_0) = \prod_{i=1}^{m} q(\mathbf{x}_{t-1}^i|\mathbf{x}_t^i, \mathbf{x}_0^i).$$
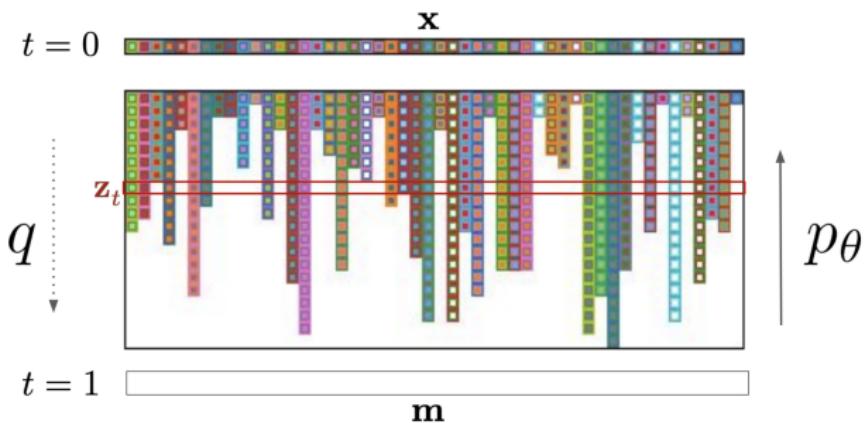

Each position i has two possible cases:

$$\mathbf{x}_t^i \neq \mathbf{e}_m \Rightarrow \mathbf{x}_{t-1}^i = \mathbf{x}_t^i, \qquad \mathbf{x}_t^i = \mathbf{e}_m \Rightarrow \mathbf{x}_{t-1}^i \in \{\mathbf{x}_0^i, \mathbf{e}_m\}.$$
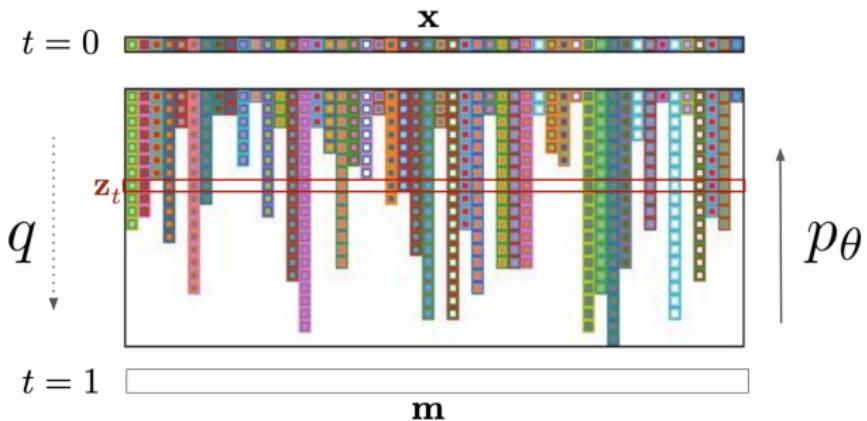

Interpretation

▶ The forward process produces **random partial observations** of the clean sequence.

▶ If a token is visible at time t, the reverse distribution is deterministic.

▶ Unmasked tokens yield a deterministic posterior and therefore contribute only a constant to the ELBO. Therefore, only masked tokens contribute to the training loss.

Interpretation

Training corresponds to optimizing a **continuous mixture of masked language modeling objectives** with different mask rates.

Algorithm: Masked Diffusion Language Model (MDLM)

Training

1. Sample $\mathbf{X}_0 \sim p_{\text{data}}(\mathbf{X})$ and $\lambda \sim w(\lambda)$.

2. Corrupt the sequence by independent masking:

$$\mathbf{x}_\lambda^i = \begin{cases} \mathbf{e}_m, & \text{with prob. } \lambda, \\ \mathbf{x}_0^i, & \text{with prob. } 1 - \lambda, \end{cases} \qquad i = 1, \ldots, m.$$

3. Predict token distributions in parallel:

$$p_\theta(\mathbf{X}_0|\mathbf{X}_\lambda) = \prod_{i=1}^m p_\theta(\mathbf{x}_0^i|\mathbf{X}_\lambda).$$

4. Compute the masked-CE loss:

$$\mathcal{L}(\theta) = \sum_{i=1}^m [\mathbf{x}_\lambda^i = \mathbf{e}_m] \left[-\log p_\theta(\mathbf{x}_0^i|\mathbf{X}_\lambda) \right].$$

Sahoo S. et al. Simple and effective masked diffusion language models, 2024

Algorithm: Masked Diffusion Language Model (MDLM)

Sampling

1. Initialize $\mathbf{X} \leftarrow \mathbf{e}_m \mathbf{1}^\top$ (fully masked).
2. For a decreasing schedule $\lambda_1 > \lambda_2 > \cdots > \lambda_L$:
   2.1 Predict $p_\theta(\mathbf{x}^i | \mathbf{X})$ for all positions.
   2.2 Unmask a subset of positions to reach the next mask rate $\lambda_{\ell+1}$ (e.g., sample tokens for newly-unmasked positions).
3. Return the final sequence $\mathbf{X}$ (fully unmasked).

Outline

Course Overview: Problem Statement

Goal

Learn a generative model $p_\theta(\mathbf{x})$ that matches the data distribution $p_{\text{data}}(\mathbf{x})$.

Three similar lenses

- **Divergence minimization:**

$$\min_\theta D\left(p_{\text{data}} \| p_\theta\right) \qquad (\text{KL, JS, Wasserstein, etc.})$$

- **Likelihood-based modeling:** maximize $\log p_\theta(\mathbf{x})$ (NF, VAE, diffusion-as-VAE).

- **Score-based modeling:** learn $\nabla_\mathbf{x} \log p(\mathbf{x})$ (DDPM / NCSN / SDE).

What We Covered: Part 1

Likelihood-based

► **Autoregressive (L1)**:

$$p_\theta(\mathbf{x}) = \prod_{i=1}^{n} p_\theta(x_i|\mathbf{x}_{1:i})$$

► **Normalizing Flows (L2, L10)**:

$$\mathbf{x} = \mathbf{f}_\theta(\mathbf{z}), \quad \log p_\theta(\mathbf{x}) = \log p(\mathbf{z}) + \log \left| \det \frac{\partial \mathbf{z}}{\partial \mathbf{x}} \right|$$

► **VAE (L3–L4)**:
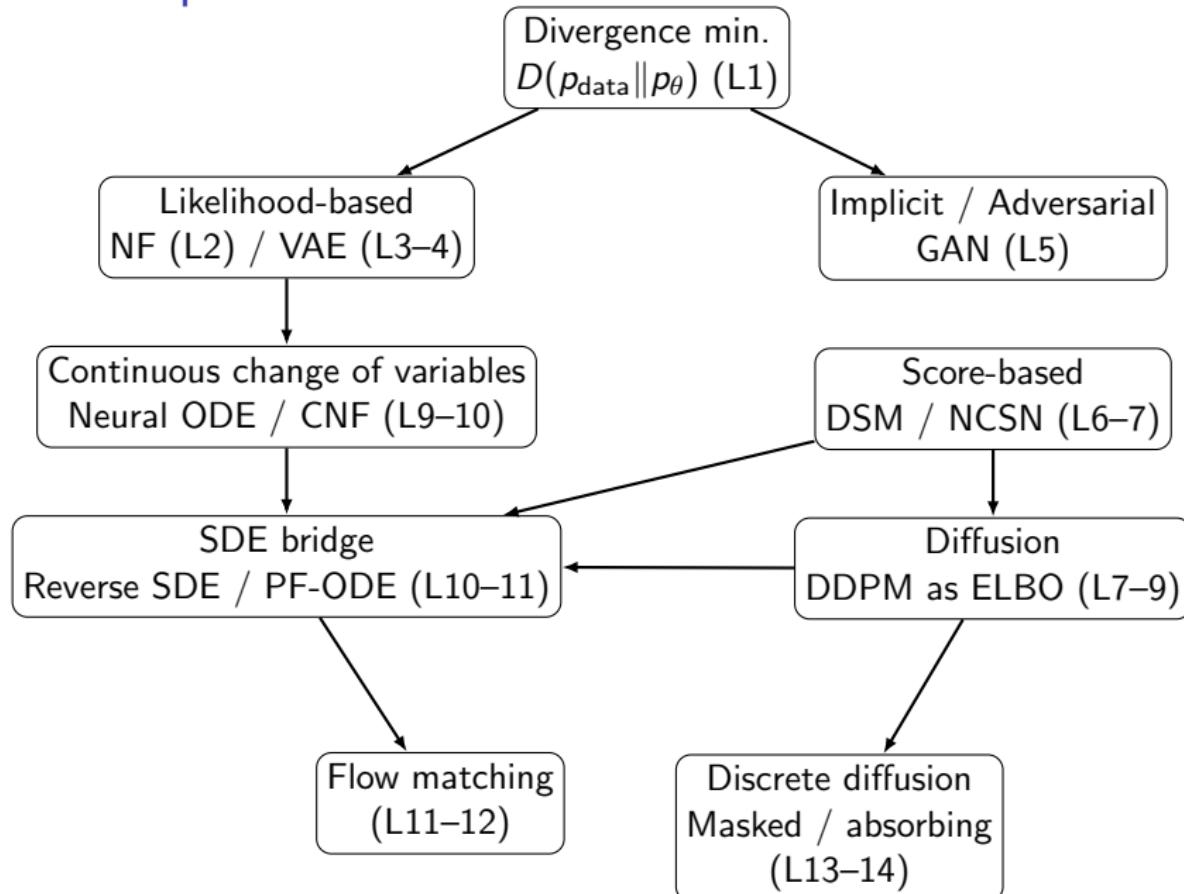

$$\log p_\theta(\mathbf{x}) \geq \mathbb{E}_{q_\phi(\mathbf{z}|\mathbf{x})}[\log p_\theta(\mathbf{x}|\mathbf{z})] - \mathrm{KL}(q_\phi(\mathbf{z}|\mathbf{x})||p(\mathbf{z}))$$

What We Covered: Part 2

Implicit / Score-based

▶ **GAN (L5)**: implicit p_θ, adversarial learning (close to JSD)

▶ **Score matching (L6)**: learn $\mathbf{s}_\theta(\mathbf{x}) \approx \nabla_\mathbf{x} \log p_{\text{data}}(\mathbf{x})$

▶ **Diffusion / DDPM (L7–L9)**: forward noising $q(\mathbf{x}_t|\mathbf{x}_{t-1})$ + reverse denoising

▶ **SDE / Flow matching (L10–L12)**: reverse SDE $\leftrightarrow$ probability flow ODE, vector field (Neural ODE) / flow matching

▶ **Discrete diffusion (L13–L14)**: Markov chain on categorical states

Generative Learning Trilemma

Rule of Thumb

- **Likelihood** & **Coverage** $\Rightarrow$ **AR / NF**   exact density, no mode dropping, *slow sampling*

- **Likelihood** & **Fast Sampling** $\Rightarrow$ **VAE**   tractable bound, fast, *blurry samples*

- **Sample Quality** & **Fast Sampling** $\Rightarrow$ **GAN**   sharp samples, *no likelihood, mode collapse*

- **Quality** & **Coverage** $\Rightarrow$ **Diffusion**   stable training, high fidelity, *slow sampling*

- **Quality** & **Faster Sampling** $\Rightarrow$ **FM / ODE**   fewer steps, continuous flows, *approx. likelihood*

- **Discrete Structure** & **Coverage** $\Rightarrow$ **Discrete Diffusion**   stable CE training, parallel denoising, *iterative decoding*

Summary

▶ For sequences, the forward process of discrete diffusionfactorize over positions, but reverse process (the model p_θ) conditions on the whole context.

▶ In the absorbing case, tokens are either unchanged or masked; so only masked tokens contribute to the ELBO loss.

▶ The discrete ELBO reduces to a MLM objective.

▶ Reparameterizing time by the mask rate $\lambda \in [0, 1]$ yields a continuous mixture of MLM losses.

▶ MDLM sampling performs iterative parallel refinement from fully masked to fully unmasked sequences.

▶ No generative model is strictly better than all others: different methods occupy different corners of the generative learning trilemma and come with unavoidable disadvantages.
